Problem 1.a

First, we'll derive π_i . The definition of the tree searching markov model leads to the following set of balance equations for the long-run state probabilities:

$$\pi_i = \pi_{i-1}q_{i-1} = \pi_0 \prod_{j=0}^{i-1} q_j$$
 for $i \ge 1$, and
$$\pi_0 = \sum_{j=0}^{\infty} \pi_i (1 - q_i)$$
 for $i = 0$.

This definition for π_0 is a bit unwelldy. We can also think of this quantity as one over the expected recurrence time, as in eq. (10.63) in the book:

$$\begin{split} \pi_0 &= \frac{1}{E(T_{0,0})} \\ E(T_{0,0}) &= 1 + \sum_{k \neq 0} p_{0,k} E(T_{k,0}) \\ &= 1 + p_{0,1} E(T_{1,0}) \\ &= 1 + p_{0,1} (1 + \sum_{k \neq 0} p_{1,k} E(T_{k,0})) \\ &= 1 + p_{0,1} (1 + p_{1,2} E(T_{2,0})) \\ &= 1 + p_{0,1} (1 + p_{1,2} (1 + \sum_{k \neq 0} p_{2,k} E(T_{k,0}))) \\ &= 1 + p_{0,1} (1 + p_{1,2} (1 + p_{2,3} E(T_{3,0}))) \end{split}$$

and so on. This unravels into a familiar closed form:

$$E(T_{0,0}) = 1 + q_0(1 + q_1(1 + q_2(1 + \dots)))$$

$$= 1 + q_0 + q_0q_1 + q_0q_1q_2 + \dots$$

$$= 1 + \sum_{i=1}^{\infty} \left[\prod_{j=0}^{i-1} q_j \right]$$

If the model is positive recurrent, then there exists some value R such that

$$R = \sum_{i=1}^{\infty} \left[\prod_{j=0}^{i-1} q_j \right] < \infty.$$

Thus,

$$\pi_i = \frac{\prod_{j=0}^{i-1} q_j}{1+R}$$
 for $i \ge 0$.

Next, $E(T_{i,0})$ follows a similar pattern.

$$E(T_{i,0}) = 1 + \sum_{k \neq 0} p_{i,k} E(T_{k,0})$$

$$= 1 + p_{i,i+1} E(T_{j+1,0})$$

$$= 1 + q_i + q_i q_{i+1} + q_i q_{i+1} q_{i+2} + \dots$$

$$= 1 + \sum_{j=i}^{\infty} \left[\prod_{k=i}^{j} q_k \right].$$

Problem 1.b

If $q_i = 0.5$ for all i, then R is a geometric series that indeed converges.

$$\pi_2 = \frac{0.5 \cdot 0.5}{1 + \sum_{i=1}^{\infty} 0.5^{i-1}} = \frac{0.25}{1+2} \approx 0.083.$$

$$E(T_{2,0}) = 1 + \sum_{j=2}^{\infty} 0.5^{j-2} = 1 + \sum_{j=1}^{\infty} 0.5^{j-1} = 1 + 2 = 3.$$

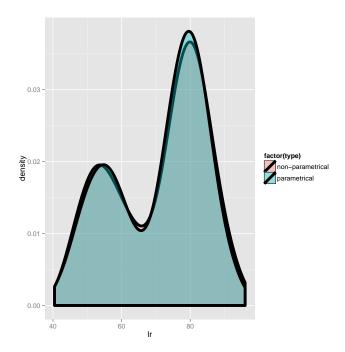

Problem 1.c

The rate of backtracking, in terms of the stationary probabilities π_i , is simply

$$\sum_{i=1}^{\infty} \pi_i (1 - q_i).$$

Problem 4

4.a-b

Appendix
